Because the objective of the research is to evaluate the effectiveness of the intervention, it is essential to ensure that the data collected are accurate and reliable. This requires a thorough understanding of the research design and the measurement tools used.

The study will use a quasi-experimental design, which allows for the comparison of outcomes between a control group and an intervention group. The control group will receive standard care, while the intervention group will receive the intervention being evaluated. Data will be collected at baseline and at two follow-up points. The primary outcome is the percentage of participants who are in remission at the end of the study. Secondary outcomes include the number of relapses, the duration of remission, and the quality of life of participants. The study will be conducted in a controlled setting to minimize the influence of external factors on the results.

The study will be conducted in a controlled setting to minimize the influence of external factors on the results.
